1 Introduction

This document is produced under the CC-by-nc-nd licence

¹© 2018-2022 the Galactic Organization. This document is licensed under CC-by-nc-nd (<https://creativecommons.org/licenses/by-nc-nd/4.0/deed.en>)

This experiment guide is a collection of all the jupyter notebooks present in the data projects.

All lines

```
print("test")
```

are python input.

And all lines

```
test
```

are python output.

By default the following colors are used for drawing concept lattices:

-  for generators;
-  for pseudo-generators;
-  for prototypes.

2 Sample data

2.1 Iris data set

2.1.1 Iris data set, limiting the cardinality of concepts

The lattice construction from the Iris data set could lead to very big lattice (several million concepts).

We can use the `Population.from_file` function to load a population in memory and the `Explorer.from_file` function to load a set of strategies described in a yaml file.

We can construct a concept lattice from a population and a list of strategies using the `ConceptLattice` class.

The Hasse diagram of a lattice can be visualized using the `HasseDiagram` class, the reduced context can be displayed using the `BinaryTable` class and the summary table can be displayed using the `ConceptTable` class.

```
from galactic.population import Population
from galactic.concepts import ConceptLattice, ConceptRenderer,
↳ ConceptTable
from galactic.algebras.poset import HasseDiagram
from galactic.algebras.relational import BinaryTable
from galactic.strategies import Explorer
from project_data import share_path
```

```
import sys
import os

data_path = os.path.join(
    share_path,
    "sample",
    "data",
    "iris",
    "iris.csv",
)

with open(data_path, "r") as data_file:
    population = Population.from_file(data_file)
population

<galactic.population.Population at 0x7f4469dfc080>

len(population)

150
```

2.1.1.1 Limiting the cardinality of concepts to 110

```
explorer_path = os.path.join(
    share_path,
    "sample",
    "data",
    "iris",
    "explorer-110.yaml",
)

with open(explorer_path, "r") as explorer_file:
    print(explorer_file.read())
    explorer_file.seek(0)
    explorer = Explorer.from_file(explorer_file)

## 3 Sequence experiments

### 3.1 String data

#### 3.1.1 Chemical Formula example

We can use the `Population.from_file` function to load a population in memory and the `Explorer.from_file` function to load a set of strategies described in a `yaml` file.

We can construct a concept lattice from a population and a list of strategies using the `Lattice` class.

The Hasse diagram of a lattice can be visualized using the `HasseDiagram` class, the reduced context can be displayed using the `ReducedContext` class and the summary table can be displayed using the `Table` class.

```
from galactic.population import Population
from galactic.strategies import Explorer
from galactic.concepts import (
 ConceptLattice,
 ConceptRenderer,
 ConceptTable,
)
from galactic.algebras.poset import HasseDiagram
from galactic_strategy_string_match_basic import (
 CompleteMatchStrategy,
 PrefixMatchStrategy,
)

## 3.2 Chain data

### 3.2.1 Wine-City data set

The Wine-City dataset is issued from the museum data “La cité du vin” in Bordeaux, France (<https://www.laciteduvin.com/en>), gathered from the visits on a period of one year (May 2016 to May 2017). The museum is a large “open-space”, where visitors are free to explore the museum the

way they want, without predetermined path. When they arrive at the museum, they receive a small personal device to detect whenever a visitor is close to an animation spot called a *module*. The museum contains 20 modules, so we can say that extracted sequences for this data is quite short. By extracting the sequences of activation of each module, we end up with a precise enough idea of what the visit looked like for each visitor of the museum.

The lattice construction from the `Wine-City` data set could lead to very big lattice (several hundred thousand concepts) and takes a lot of time to preprocess. Here we select random portion from the dataset to test our strategies, also we may use the meta strategies to limit the generation of concepts according to the support or confidence.

We can use the `Population.from_file` function to load a population in memory and the `Explorer.from_file` function to load a set of strategies described in a `yaml` file.

We can construct a concept lattice from a population and a list of strategies using the `Lattice` class.

The Hasse diagram of a lattice can be visualized using the `HasseDiagram` class, the reduced context can be displayed using the `ReducedContext` class and the summary table can be displayed using the `Table` class.

)
```

### 3.3 Sequence data

#### 3.3.1 Daily-Actions data set

The Daily-Actions dataset is a small database of sequences that represents daily actions of 25 individuals of L3i laboratory<sup>1</sup>, where a daily action can be [*Wakeup, Breakfast, Work, Dinner*..].

We can use the `Population.from_file` function to load a population in memory and the `Explorer.from_file` function to load a set of strategies described in a `yaml` file.

We can construct a concept lattice from a population and a list of strategies using the `Lattice` class.

The Hasse diagram of a lattice can be visualized using the `HasseDiagram` class, the reduced context can be displayed using the `ReducedContext` class and the summary table can be displayed using the `Table` class.

### 3.4 Interval data

#### 3.4.1 Wine-City data set

The Wine-City dataset is issued from the museum data “La cité du vin” in Bordeaux, France (<https://www.laciteduvin.com/en>), gathered from the visits on a period of one year (May 2016 to May 2017). The museum is a large “open-space”, where visitors are free to explore the museum the way they want, without predetermined path. When they arrive at the museum, they receive a small personal device to detect whenever a visitor is close to an animation spot called a *module*. The museum contains 20 modules, so we can say that extracted sequences for this data is quite short. By extracting the sequences of activation of each module, we end up with a precise enough idea of what the visit looked like for each visitor of the museum.

The lattice construction from the Wine-City data set could lead to very big lattice (several hundred thousand concepts) and takes a lot of time to process. Here we select random portion from the dataset to test our strategies, also we may use the meta strategies to limite the generation of concepts according to the support or confedence.

We can use the `Population.from_file` function to load a population in memory and the `Explorer.from_file` function to load a set of strategies described in a `yml` file.

We can construct a concept lattice from a population and a list of strategies using the `Lattice` class.

The Hasse diagram of a lattice can be visualized using the `HasseDiagram` class, the reduced context can be displayed using the `ReducedContext` class and the summary table can be displayed using the `Table` class.

```
 from galactic.population import Population
from galactic.strategies import Explorer
from galactic.concepts import (
 ConceptLattice,
 ConceptRenderer,
 ConceptTable,
)
from galactic.algebras.poset import HasseDiagram
from galactic.algebras.relational import BinaryTable

### 3.4.1.1 Simple Match Strategy

```
explorer_path = os.path.join(
 share_path,
 "sequence",
 "data",
 "explorers",
 "interval-sequence",
 "atf-match-basic.yaml",
)
with open(explorer_path, "r") as explorer_file:
 print(explorer_file.read())
 explorer_file.seek(0)
 explorer = Explorer.from_file(explorer_file)
```

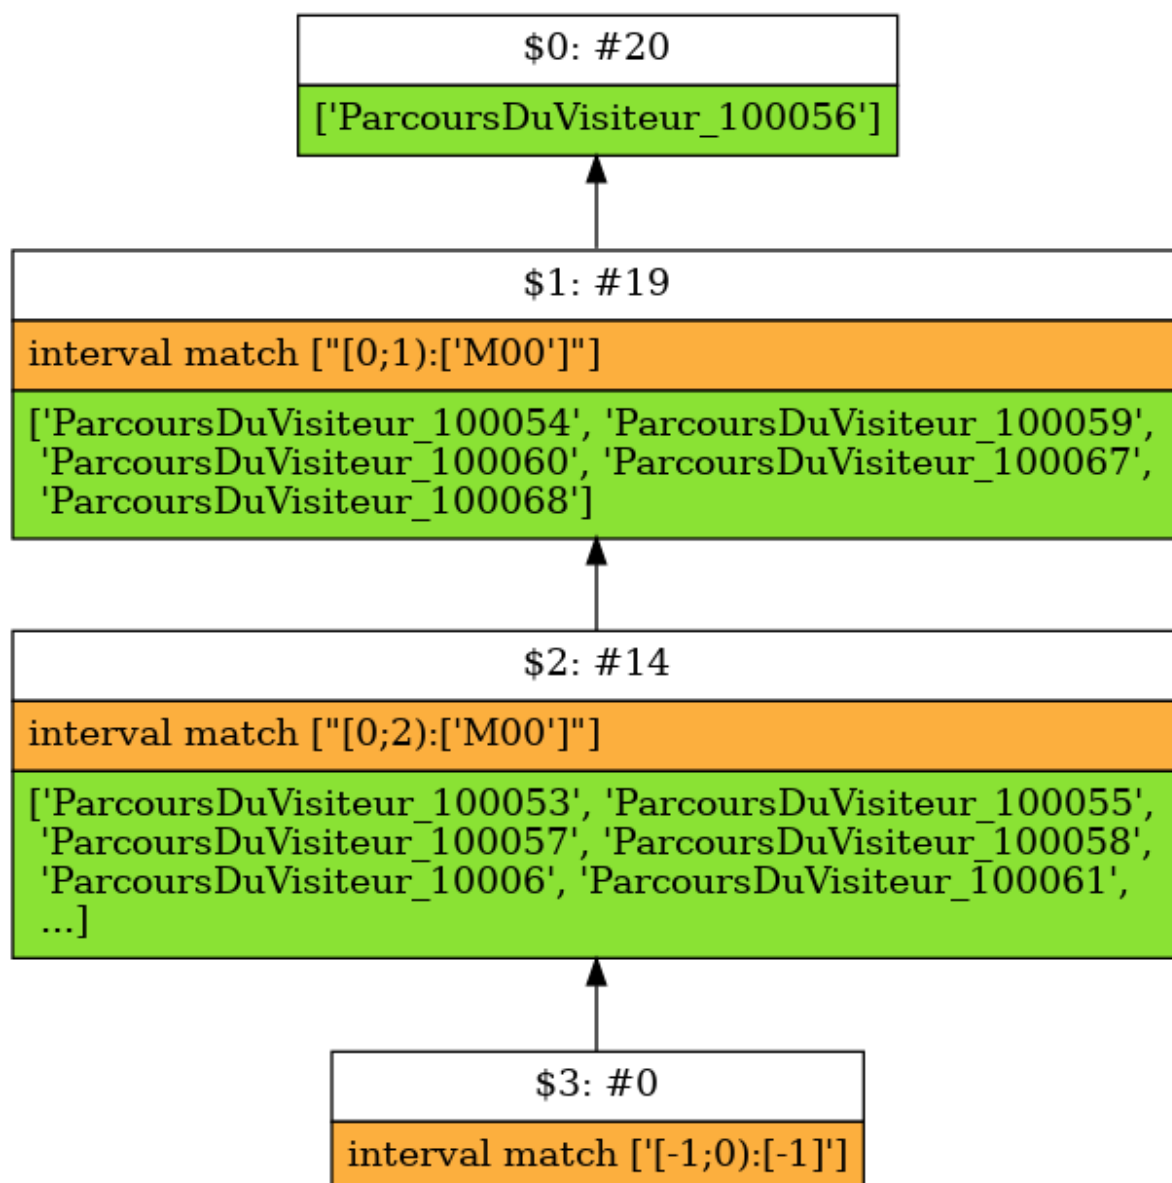

```
characteristics:
- !characteristic.interval.Interval
 characteristic: !characteristic.core.Key
 name: "interval"
descriptions:
- !description.interval.MaximalCommonInterval
 - *id001
strategies:
- !strategy.interval.intersection.basic.AlphabetTimeFrame
 arguments:
 - *id001
```

```
lattice = ConceptLattice.create(
 population=population,
 descriptions=explorer.descriptions,
 strategies=explorer.strategies,
)
```

```
HasseDiagram(
 lattice,
 domain_renderer=ConceptRenderer(),
)
```

```
BinaryTable(
 lattice.reduced_context,
 domain_renderer=ConceptRenderer(join_irreducible=True),
 co_domain_renderer=ConceptRenderer(meet_irreducible=True),
)
```

### 3.4.2 GeoLuciole data set

Is issued from classical GPS trajectories of people's displacements in the city of La Rochelle in France. By matching the GPS coordinates to districts of the city, raw data are transformed into semantic sequences. The data have been collected by a specific application named GeoLuciole that we have developed for the DA3T1. project. The data contains only 15 trajectories with an average size of sequences equals to 2 2.

1 : System for the Analysis of Numerical Traces for the development of Tourist Territories (Dispositif d'Analyse des Traces numériques pour la valorisation des Territoires Touristiques)

2 : It was planned to collect more data during the holidays on Mars and April, but unfortunately, this was impossible due to the world pandemic Covid-19

```
